The wine industry

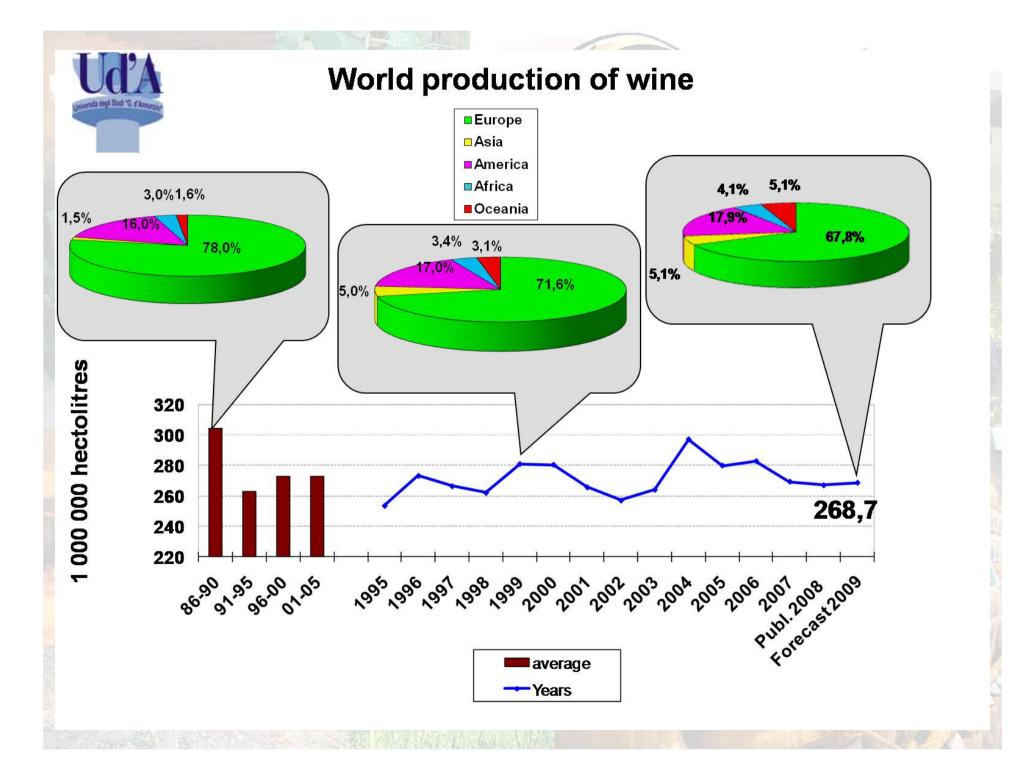

The wine industry is a "global" sector which represents a significant demand of world

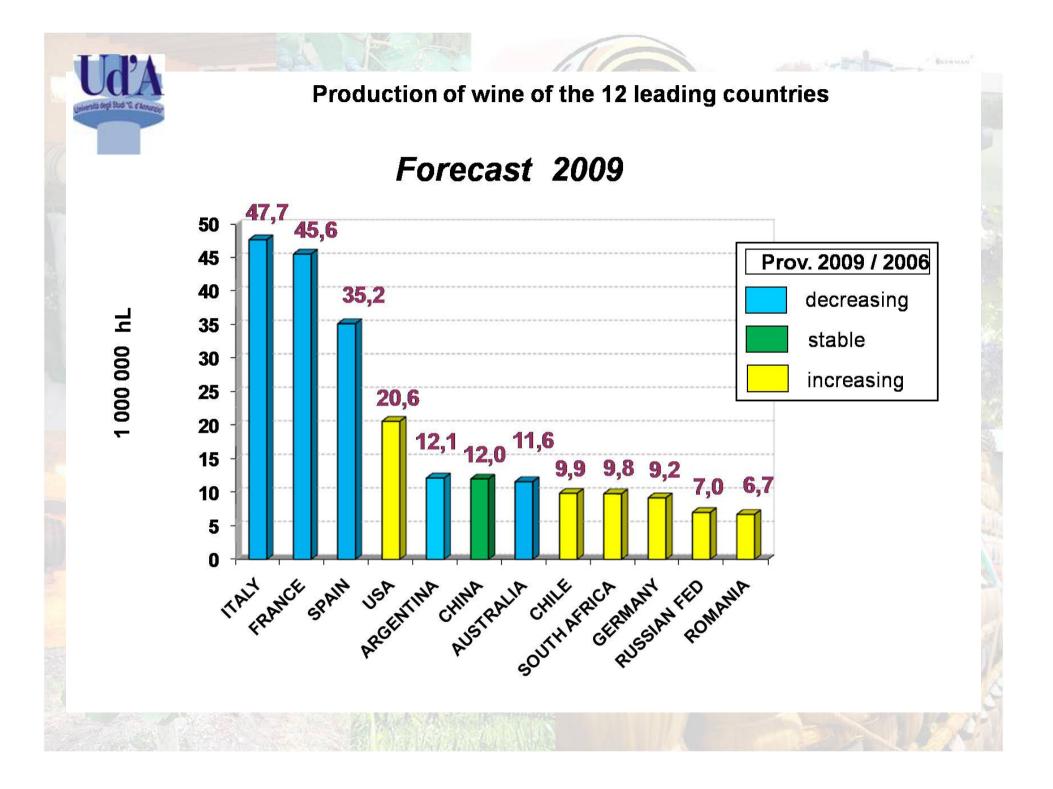

res<mark>our</mark>ces.

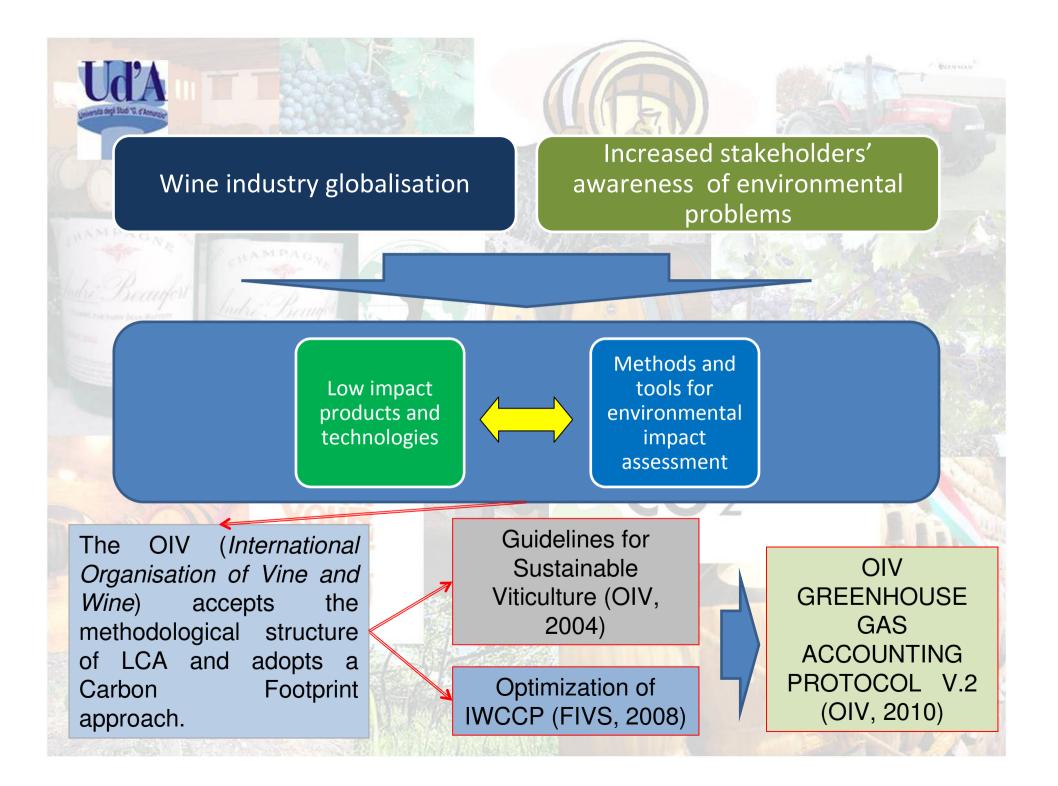

Worldwide, 8 million hectares are used for viticulture

Annual world production of wine is about 270 million hectolitres (OIV, 2006)

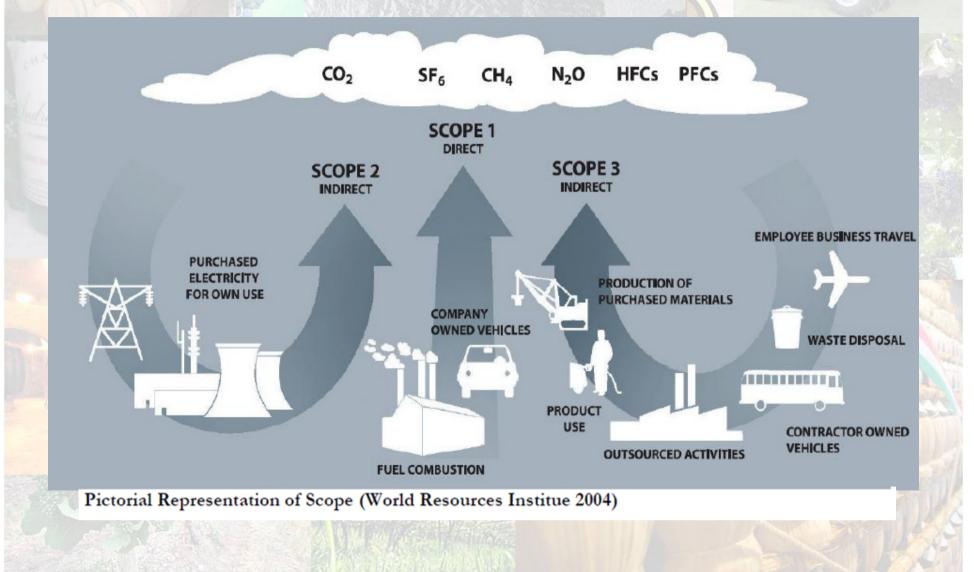

IWCCP 3-scope framework

Aim of this work

Application of the Carbon Footprint to a winery in Abruzzo, Italy, where an LCA had been already carried out previously (Petti et al., 2005, 2006).

Analysis, in a context already known, of an instrument (CF) which is still being defined by the OIV .

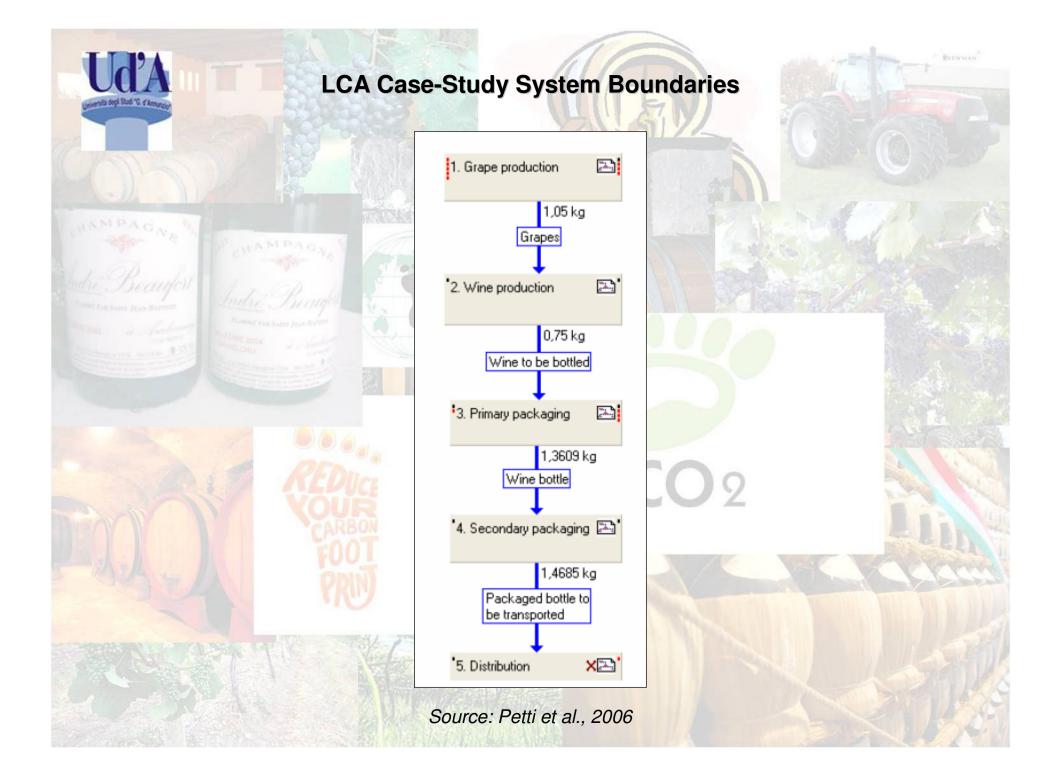

Preliminary comparative considerations between the two tools considered (LCA and CF). The functional unit chosen was a bottle (750 ml) of organic red wine (Montepulciano d'Abruzzo),

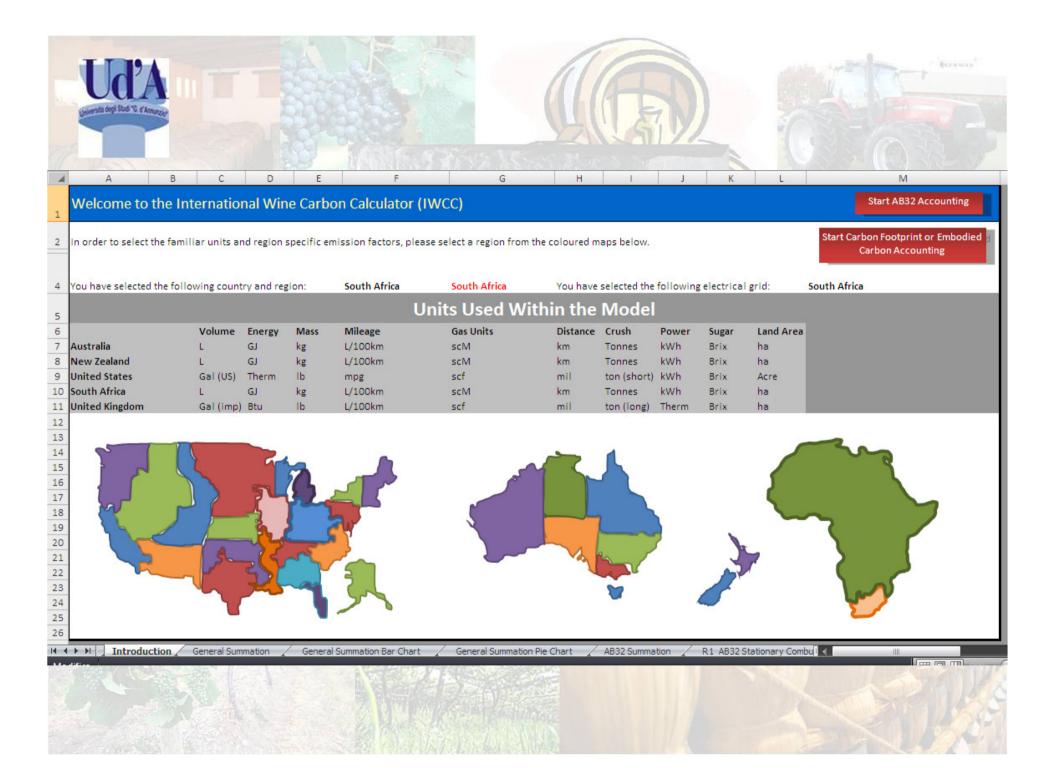

The farm analysed has 12 hectares of vineyard, 5 of which cultivated with Montepulciano d'Abruzzo grape.

The average yearly production of Montepulciano grapes is about 70 tonnes.

The yearly production of wine is about 50,000 litres, part of which (75%) is bottled, whilst the remaining is sold in bulk.

Implementation of the CFP Scope 1

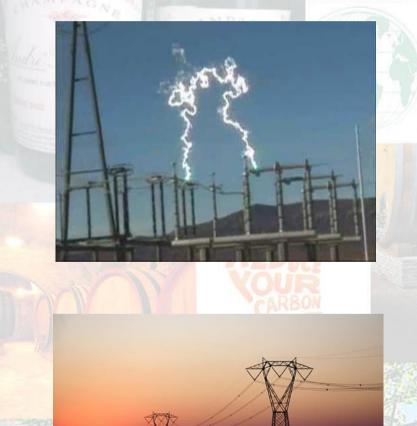

Mobile equipment: the carbon calculator allows the user to select the fuel type, but not the kind of equipment (tractor, lorries, etc); thus, fuel-specific CO_2 default emission factors were used in calculations, irrespective of the piece of equipment actually used.

Waste disposed of on-site: the amount of shredded grape stalks spread on fields and buried as a soil improver were entered in the "landfilled grape marc, pommace, grape stalks and stems" item.

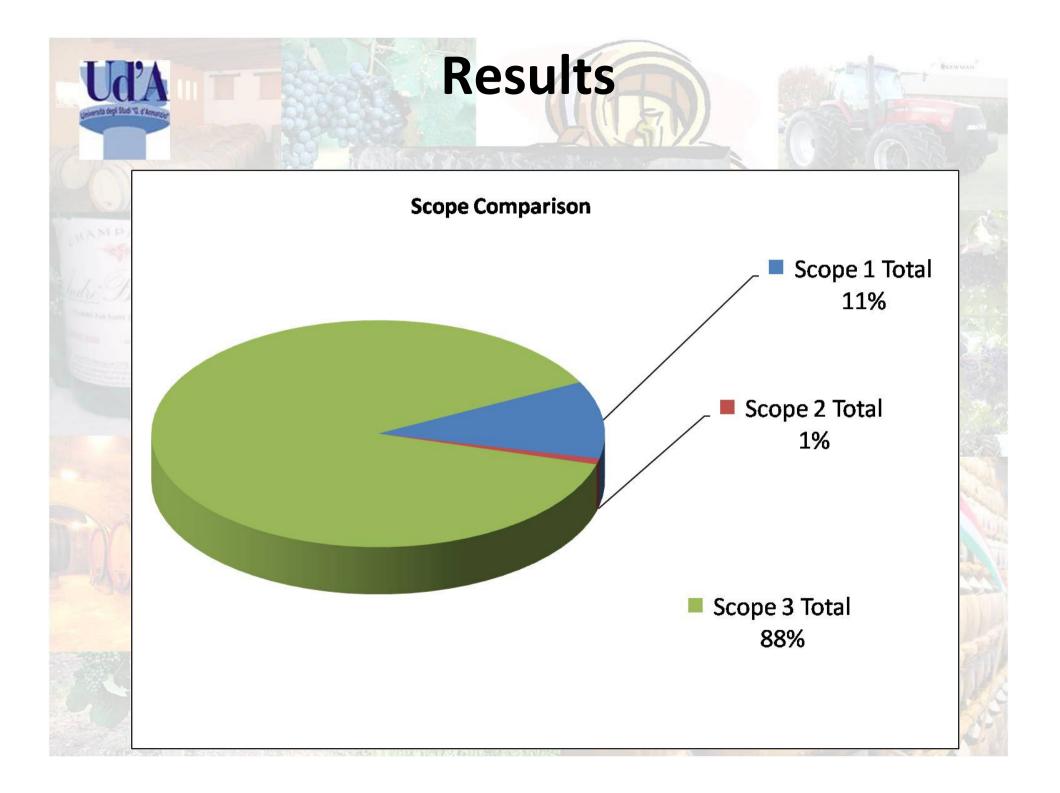

Implementation of the CFP Scope 2

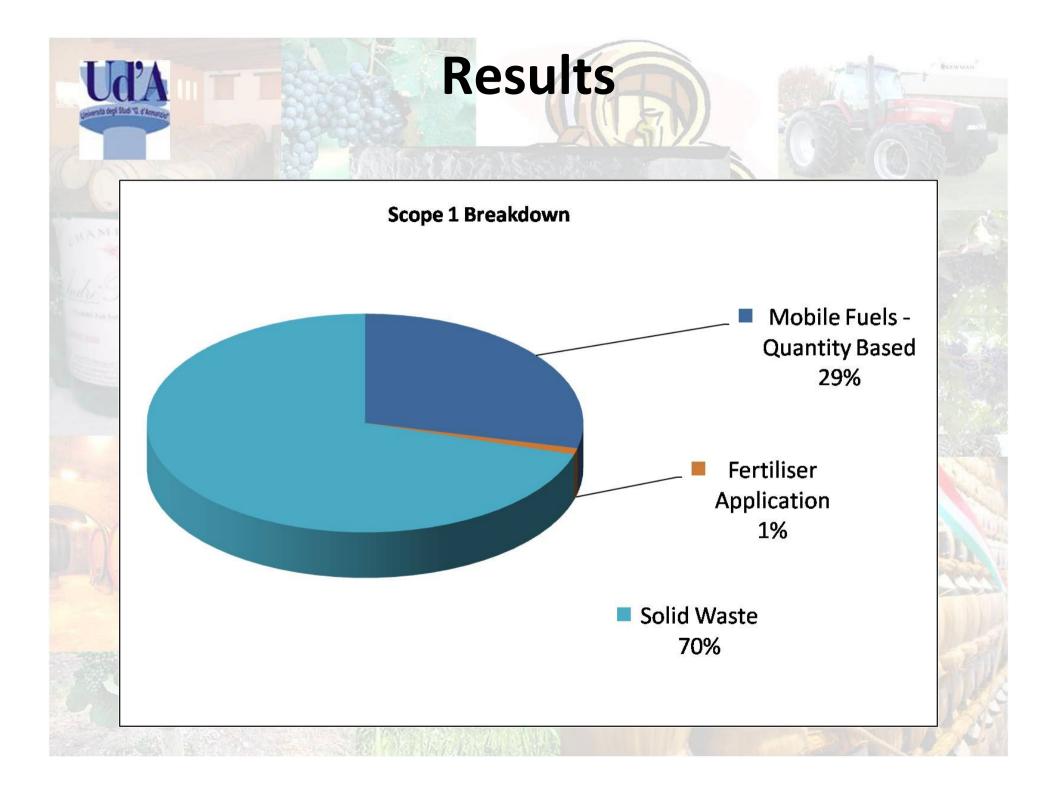

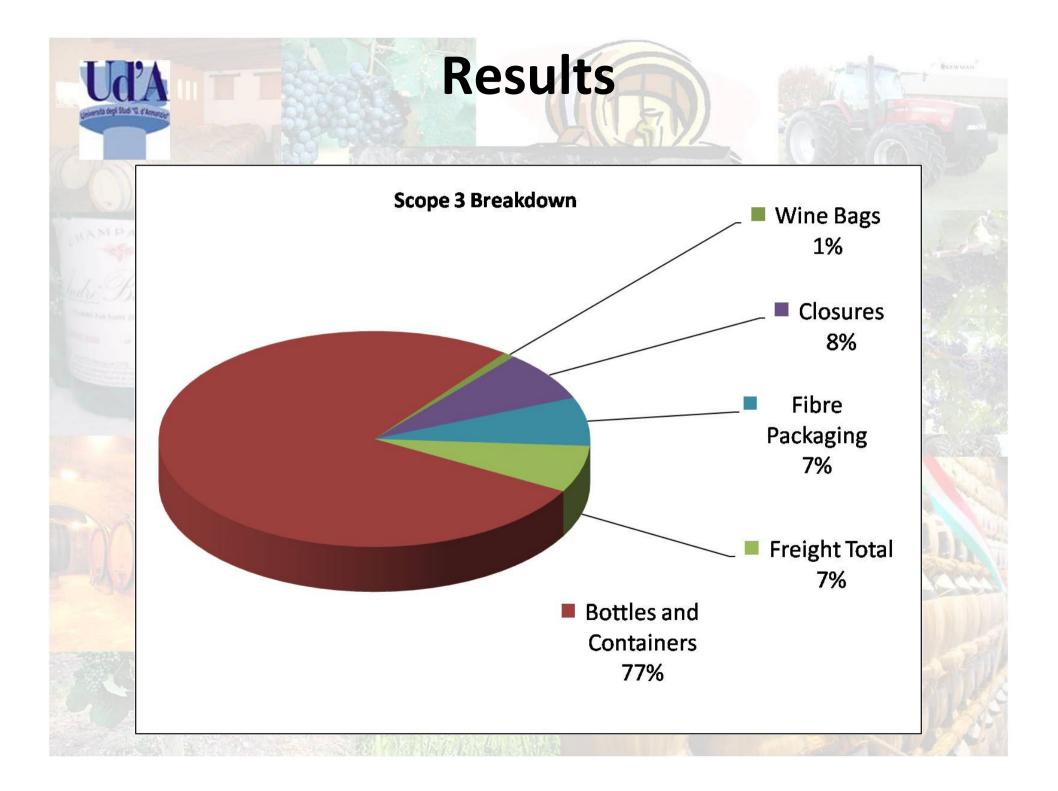

- CO₂ emission factor for power generation: it was adapted to the Italian power mix (source: ELCD).
- No specific correction factor for power transmission and distribution losses was entered in the relevant field of the IWCC.

Implementation of the CFP Scope 3

- Packaging: no specific data field was found for the bottle paper labels.
- Transports: overall amount of kilometres travelled by the different types of vehicles used for product distribution were calculated.
- Wine related products: "bentonite" the only one for which a corresponding entry was found.
- No relevant entries were found for: potassium metabisulphite, yeast, albumin, chemicals and other inputs used in the bottling process (sodium hydroxide, nitrogen), as well as in agricultural practices (copper hydroxide, micronized sulphur, *Bacillus thuringiensis* bacteria, milk, glucose).
- Waste: marc and lees are delivered to a distillery for further processing. It was decided not to enter any data within these items. Indeed, a more accurate modelling would require an allocation process (or alternative approaches) to deal with the environmental burden shared by the main product and by-products; no allocation (or alternative option) seems to be possible in the IWCC.

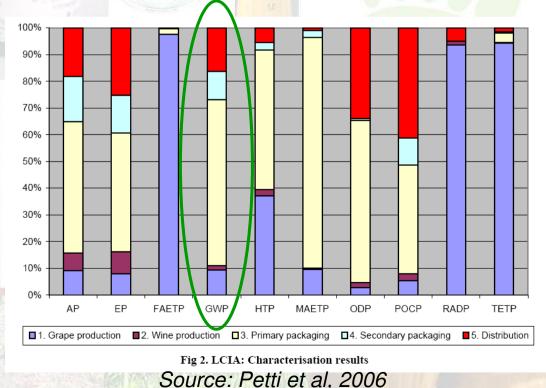

LCA ⇔ CFP

Good agreement. In LCA case-study the major contribution in terms of GWP (more than 70%) comes from packaging (in particular: the glass bottle), followed by the product distribution and the agricultural operations.

IWCC limitations

Most default model parameters and assumptions are closely related to specific Countries/Regions The list of products and inputs available is limited to just a few wine related products Specific modelling options for co-products are lacking (allocation, system expansion) (marc, lees, wine; bottled and bulk wine)

The same applies for recovered waste (avoided impacts) (grape stalks)

Burden/impact shifting issues

Conclusions

- The wine industry has been increasingly impelled by market and regulatory drivers to assess and reduce carbon emissions
- As expected, despite a few differences in framework and modelling, results concerning global warming are rather consistent
- About the CF tool, the lack of accurate baseline data was confirmed and the need of further improvement and adaptation to additional contexts was highlighted
- The calculator carries out an accurate assessment of emissions as it contains effective tools capable of providing concise information analysing all phases of wine production
- LCA seems to be more effective in avoiding environmental burdens and impacts to be shifted from one life-cycle step to another, or from one environmental concern to another.
- On the other hand CF seems to be more suitable as a marketing tool

Thank you!
